Introduction

My notes on using git as a data scientist. In other words you *know and accept* you should be using git but man is it confusing and almost painful. ~_(ツ)_/~

I've been a software developer and data scientist for more than 30 years and I've used all sorts of version control systems (started with Apollo DSEE, look that one up). I find git confusing.

Moving from SVN to Git

- <https://smartbear.com/blog/migrating-from-subversion-to-git-lessons-learned/>
- <https://dev.to/fpuffer/what-makes-companies-switch-from-svn-to-git-3687>
- <https://ohshitgit.com/>

Git setup in general

- <https://happygitwithr.com/>
- <https://happygitwithr.com/git-intro.html>

GitHub Access Tokens

Github now requires you to use personal access tokens (PATs). These are a bit of a pain but described by Jenny Bryan here:

- <https://happygitwithr.com/https-pat>

GitHub Push Issues

Today (2024-08-31) I was setting up a new repo with admittedly some large `.graffle` files. I got this error

```
rob@Taylor Platform_Terrace_Shed % git push -u origin main
Enumerating objects: 69, done.
Counting objects: 100% (69/69), done.
Delta compression using up to 10 threads
Compressing objects: 100% (69/69), done.
error: RPC failed; HTTP 400 curl 22 The requested URL returned error: 400
send-pack: unexpected disconnect while reading sideband packet
Writing objects: 100% (69/69), 11.63 MiB | 19.02 MiB/s, done.
```

```
Total 69 (delta 25), reused 0 (delta 0), pack-reused 0
fatal: the remote end hung up unexpectedly
Everything up-to-date
```

This happened in RStudio and in a Mac Terminal window. Over to stackoverflow to this link

- <https://stackoverflow.com/questions/78590144/while-cloning-the-git-repository-getting-unexpected-disconnect-while-reading-sid>

Which says increase a git config setting. So I did that and everyone is happy.

```
rob@Taylor Platform_Terrace_Shed % git config http.postBuffer 10g

rob@Taylor Platform_Terrace_Shed % git push -u origin main
Enumerating objects: 69, done.
Counting objects: 100% (69/69), done.
Delta compression using up to 10 threads
Compressing objects: 100% (69/69), done.
Writing objects: 100% (69/69), 11.63 MiB | 46.15 MiB/s, done.
Total 69 (delta 25), reused 0 (delta 0), pack-reused 0
remote: Resolving deltas: 100% (25/25), done.
To https://github.com/StatsResearch/Platform_Terrace_Shed.git
 * [new branch]      main -> main
branch 'main' set up to track 'origin/main'.
rob@Taylor Platform_Terrace_Shed %
```

Lightbulb Moments

Switching back and forth between main and branches

This is from the world famous Jenny Bryan ¹

- <https://happygitwithr.com/git-branches.htmlSection22.2>

So you *can* do it and yes git **stash** is a way but she recommends the same idea I had read somewhere else about *always* doing a commit even if it is just with the comment ‘WIP xxx’. But she then goes on to explain how you can get rid of that temporary commit using terminal (bash) commands like:

¹If you don't know who she is look at this link <https://www.rstudio.com/speakers/jenny-bryan/> and follow her on twitter: @JennyBryan.

```
$ git checkout issue-5
$ git reset HEAD~
```

Merge conflicts

- <https://happygitwithr.com/git-branches.html> Section 22.4

Daily routine

```
1 # fetch the changes from the remote
2 $ git fetch origin
3
4 # show commit logs of changes
5 $ git log master..origin/master
6
7 # show diffs of changes
8 $ git diff master..origin/master
9
10 # apply the changes by merge..
11 $ git merge origin/master
12
13 # .. or just pull the changes
14 $ git pull
```

I Just Want To Rename A File (git mv)

Hold on to your hat.

1. Make sure everything is committed i.e. you don't have any work in progress.
2. Use the `git mv` command
 - % `git mv -v old-name.R new-name.R`
 - Using `git mv` rather than just `mv` means the file is automatically 'staged' for you. All you need to do now is 'commit it with a suitable message.'
3. Do a `git status` to double check
 - % `git status`
4. Do the commit
 - % `git commit -m "Renamed file"`
 - (*you could of course use the RStudio Git menus for this bit*)

Marking Something as Significant (git tag)

If you want to be able to refer to a commit without using the odd looking SHA1 you need to use git tag. You do this *after* the commit which you want to mark.

```
$ git tag -a v1.4 -m "my version 1.4"
```

Don't put quotes round the -a bit

- <https://www.atlassian.com/git/tutorials/inspecting-a-repository/git-tag>

Then once you have done that you need to push the tag up to the remote.

```
$ git push --tags
```

If you just want to see what tags you have

```
$ git tag -l
```

Which only give you the tag 'ref name'

What you probably wanted was this

```
$ git tag --format "%(refname:short) | %(taggerdate:iso) [%(contents:subject)]"
--sort=-taggerdate:iso
```

Do the above all on one line. How painful is that ~_(_)/~.

Tagging A Specific Commit (with the correct date)

Sometime you may want to clean things up by putting a tag on an *older* commit and make it fit in with some naming scheme you have come up with. This link and bash code snippet will do that *importantly making the tag use the correct date of the older commit*.

See this link

- <https://stackoverflow.com/questions/4404172/how-to-tag-an-older-commit-in-git/21759466#21759466>

```
# Set the HEAD to the old commit that we want to tag
git checkout 9fceb02

# temporarily set the date to the date of the HEAD commit, and add the tag
GIT_COMMITTER_DATE="$(git show --format=%aD | head -1)" git tag -a v1.2 -m"v1.2"

# Make sure the above is a SINGLE line at the command prompt.
```

```
# TWO commands will not work.

# push to origin
git push origin --tags

# set HEAD back to whatever you want it to be
git checkout master
```

How Do I Compare Two PDF Output Files

Well you would think this is easy eh? But the problem is the fact that it is a .pdf file i.e. **not** a text file. So what you need to do is get the older version's commit SHA1 and then extract that particular commit to somewhere different. Note this command below is extracting the *whole folder structure* at the point in time from your SHA1.

From this link:

- <https://stackoverflow.com/questions/11018411/how-do-i-export-a-specific-commit-with-git-archive>

```
$ git archive --format zip --output ./CompareResults/Cmp-01.zip 4081d45d
```

Using the above command you have the whole repo as at SHA1 4081d45d in the zip file Cmp-01.zip

You can of course just pull out a specific file using this command:

```
$ git archive --format zip --output ./CompareResults/SingleFile.zip 4081d45d

Prospec_Stg_1_N69_ELvsDP.pdf (all on a single line)
```

Getting Info

Sometimes you just wish you could ask a simple question `_(_)/`.

Order the branches by time and give me some context

```
$ git branch -vv --sort=-committerdate
```

Find out what branch a commit came from

This command also shows you what branches it is in

```
$ git branch --contains ec0b406e -vv --sort=-committerdate
```

Where the `ec0b406e` is the SHA1 hash you are interested in. The output is reverse time ordered so look for the bottom one to see where it started out in life.

Is my file being tracked by git?

The simple answer is:

```
$ git ls-files
```

As you'll probably expect by now you can get an uber nerd answer as well, see this:

- <https://stackoverflow.com/questions/15606955/how-can-i-make-git-show-a-list-of-the-files-that-are-being-tracked/15606998>

Tag Info

- <https://stackoverflow.com/questions/13208734/get-the-time-and-date-of-git-tags>

Am I connected to a remote?

This is most likely to be GitHub.

```
$ git remote -v
```

This should get you something like:

```
Taylor:Teaching_Survival_Git rob$ git remote -v
origin  https://github.com/StatsResearch/Teaching_Survival_Git.git (fetch)
origin  https://github.com/StatsResearch/Teaching_Survival_Git.git (push)
Taylor:Teaching_Survival_Git rob$
```

Note that if you are *not* connected to a remote you get no output from the command. Which might be hard to spot.

Another way to do it is to use the command

```
$ git remote show origin
```

This will give you something like this if you are connected to a remote

```
Taylor:Teaching_Survival_Git rob$ git remote show origin
* remote origin
  Fetch URL: https://github.com/StatsResearch/Teaching_Survival_Git.git
  Push URL: https://github.com/StatsResearch/Teaching_Survival_Git.git
  HEAD branch: main
  Remote branch:
    main tracked
  Local branch configured for 'git pull':
    main merges with remote main
  Local ref configured for 'git push':
    main pushes to main (up to date)
Taylor:Teaching_Survival_Git rob$
```

If you are *not* connected to a remote you'll get this slightly scary output but it at least tells you something.

```
Taylor:GaggiaClassic rob$ git remote show origin
fatal: 'origin' does not appear to be a git repository
fatal: Could not read from remote repository.

Please make sure you have the correct access rights
and the repository exists.
```
